ABSTRACT
The past few years have witnessed an explosive growth in the use of smartphones as the enabling technology for accessing Internet based services, as well as for personal communication needs in networking environments. The recent surge in popularity of smart hand held devices, the Google Android operating system as one of the dominate technology trends for the smartphones is virtualization platform that provides an application oriented services to smartphones infrastructure. Android devices have appeared so strongly and, since then, the number of applications available for this operating system has exponentially increased, Google already has its Android market where applications are placed and offered to the smartphone users. Due to the gain in popularity of android based smartphones, has given a new challenges in protection of end user privacy. The current android-based Location and text message sharing system is work only single user perspective to share the information with other user having poor user interface that user can’t manage to understand easily. In the proposed paper describe to overcome the drawback of the current developed system that provides the secure communication of the user data like text message and user location by developing more healthy user interface that can easily managed to understand by the end user. The proposed system also helps to share information within that group and achieve the accuracy of information.

Keywords: Android, App Inventor for Android, Smart Gadget.

1. Introduction
Technology trends in both hardware and software have driven the hardware industry towards smaller, faster and more capable mobile hand-held devices that can support a wider-range of functionality and open source operating systems. Mobile hand-held devices are popularly called smart gadgets.[1] The smart gadget life-cycle has evolved drastically in recent years. These new generations of the smart gadget devices such as the iPhone and Google Android devices are powerful enough to accomplish most of the tasks that previously required a personal computer. Among them, Google Android has been gaining popularity and its market share in the mobile operating system market is rapidly increasing. According to Gartner (2010) [2] Android is poised to become second worldwide mobile operating system in the nearer future. Android is a widely anticipated open source operating system for smartphones. Developed by the Open Handset Alliance (visibly led by Google) initially release in September 23, 2008. [3] It provides a base operating system, an application middleware layer, a Java software development kit (SDK), and a collection of system applications. [4] Android phones ship with a rich array of built-in activities including different applications developed under the android platform or the application framework provided by the android. In July 2010, Google announced the public beta release of the App Inventor for Android (AIA) visual programming environment. [5] App Inventor for Android (AIA) provides a platform to develop the new set of applications in the open source environment of Android operating system.

Using the technology, the many applications have been develop in the recent years. As per the survey the gaining popularity of social networking sites like Facebook, Twitter the different mobile application is develop to transmit the information through different peoples. Android based smart phones applications and internet; people are sharing information with other people but they are not sure that information is securely transmitted or not, these proposed system deals with secure transmission of information with each other within the network. The main objective of this proposed system, on the highest level, is to communicate with a PHP server that stores the information sent through the android device in encrypted form and vice-versa which finally establish a secure two way communication between android device and web server.

2. Related Works
Adding text messaging functionality to mobile devices began to gain traction in the mobile communication services community in the early 1980s. The first action plan of the CEPT Group GSM was approved in December 1982, requesting “The services and facilities offered in the public switched telephone networks and public data networks should
be available in the mobile system. [6] This plan included the exchange of text messages either directly between mobile stations, or transmitted via Message Handling Systems widely in use at that time. The first proposal which initiated the development of exchanging information or sent message to the user was made by a contribution of Germany and France into the GSM group meeting in February 1985 in Oslo. [7] Initial growth was slow, with customers in 1995 sending on average only 0.4 messages per GSM customer per month. In 2013, 6.1 trillion text messages were sent. [8] This translates into 193000 SMS per second. [9] While SMS reached its popularity as a person-to-person messaging, another type of SMS is growing fast: application-to-person (A2P) messaging. A2P is a type of SMS sent from a subscriber to an application or from an application to a subscriber. It is commonly used by financial institutions, airlines, hotel booking sites, social networks, and other organizations sending SMS from their systems to their customers. According to research in 2013, A2P traffic is growing faster than P2P messaging traffic. [10]

Over the years several approaches and solutions presented considering the secure exchanging of message thorough client and webserver. The various researches have been done and are going on location based project and in the same ratio various applications have been developed on location-based and message sharing system. [11] As the amount of user deal to exchange the information with other people to store the large amount of data the existing system cannot support the centralized database. Sensitive data may also be leaked accidentally due to improper disposal or resale of storage media. [12] Diesburg et al. [13] surveys, summarizes, and compares existing methods of providing confidential storage of data but it cannot support the secured communication between the user application and the webserver. Ramesh Shrestha, Yao Aihong et al. [14] developed location and message sharing system for Android Platform. In the present location based services, the works are mainly focused on how to handle the location, how to display Google map on android devices and finally about classes and functions used for location services.

3. Proposed Methodology:

3.1 Preface and Equitable:

Mutual secured communication between android application and web server for exchanging of information must be adopted by the system in order to achieve high security level and overcome the lots of security vulnerabilities. The main objective of the system, we try to propose our solution to secure user messages and location information from unauthorized access. We are trying to achieve the mutual communication between android application and web server by using two way secured communications by encrypting the message and by using key exchange algorithms with centralized database. Our system also proposed to information exchange between user groups using more user friendly interface. The main objective of our system is on the highest level,

1. To communicated with android application with Webserver for message exchange. The secured communication is done by using several encryptions algorithms to encrypt and decrypt the message that are stored over centralized database.

2. Maintain the different group of user to share information within the particular groups only. In the proposed system provides the feature to maintain the group for the specific users that can communicated within a particular group only and gives the accuracy of information within a group.

3. The proposed system implement the better user interface for the android device as well as web server that easy to achieve the high level interaction between user and application and application and web server.

4. It also achieved the goal of portability of different version of android operating system. The system will work on different version of android operating system with give level of application programming level (API).

4. Conclusion:

This paper introduced a security service for Smartphone’s, which offloads the secure message transfer and location sharing between the user and webserver. As Smartphone’s are very much popular the different kind of application for the information exchange and location sharing but it violated the security on the certain level that causes the loss of information and misuse of it by unauthorized user we introduce a new approach to deal with security while exchange information between users using different algorithms. Also literature review section covers all the related work which has been previously carried out related to this topic.
